For week four's task I used two binary searches, one to find the index of the lowest DateTime element above the lower range parameter, and another to find the highest DateTime element below the upper range parameter, and then I filled a new array with the elements from the lower range index to the higher range index. For week five's assignment I used a tree and populated it by adding nodes to either directly to the node if it was empty, or to the left or right depending on whether or not the DateTime was before or after node of the TreeNode. It is then traversed unfortunately with my generic queue which means it isn't in order like it would have been with a stack. I then implemented a recursive function to add elements to a queue based on the lower and upper ranges like before.

I struggled to implement the function that could find the elements within the upper and lower ranges for the tree, before finding the recursive function online. The array based binary search took some time as well but researching on w3school clarified a lot. The MergeSort algorithm also required reading through w3schools a lot.
